UBER RIDE 2024 OPERATIONAL & CUSTOMER ANALYSIS

Akilan

The **Uber Ride 2024 analysis** shows strong overall demand but highlights clear operational and retention challenges. The platform recorded **150K total bookings** and **93K completed rides**, supported by high service quality with an average **driver rating of 4.23** and **customer rating of 4.40**. Revenue performance is healthy and diversified across vehicle types, indicating that users continue to rely on Uber for a wide range of mobility needs throughout the year.

Revenue and ride volumes are driven primarily by **Auto, Go Mini, and Go Sedan** categories. Auto leads both in revenue (≈ **$11.73M**) and completed rides (≈ **23K**), followed by Go Mini and Go Sedan. Bike and eBike contribute meaningfully to short-distance travel, while premium categories such as Premier Sedan and Uber XL play a smaller but strategic role. Monthly booking trends remain stable, with no sharp seasonality, suggesting consistent year-round demand.

Despite strong usage, **post-booking drop-offs are significant**. The platform experienced **10.5K customer-cancelled rides**, **27K driver-cancelled rides**, and **9K incomplete rides**. Customer cancellations are mainly driven by **wrong addresses**, **changes of plans**, and **drivers not moving toward pickup locations or asking customers to cancel**, indicating coordination and reliability issues at the pickup stage. Driver cancellations are largely linked to **customer-related issues, health concerns, vehicle problems, and passenger limit violations**, reflecting safety and operational constraints.

Incomplete rides are evenly distributed across **customer demand issues, vehicle breakdowns, and other operational problems**, showing that both demand-side uncertainty and fleet reliability affect completion rates. These cancellation and incompletion patterns reduce overall efficiency and directly impact the user experience, even though satisfaction ratings remain high.

The **VTAT vs CTAT** analysis provides further insight into operational efficiency. **Vehicle Turn-Around Time (VTAT)** represents the average time a vehicle takes to become available for the next ride after completing one, while **Customer Turn-Around Time (CTAT)** reflects the total time a customer spends from booking to ride completion. Lower VTAT indicates better fleet utilization, while lower CTAT signals a smoother and faster customer experience.

Across vehicle types, VTAT generally trends downward, suggesting improving vehicle availability and operational efficiency, particularly for high-volume categories such as **Auto and Go Mini**. CTAT, however, remains relatively higher and more variable, especially for larger or premium vehicle types. This gap indicates that even when vehicles are available, customers may still experience delays due to **pickup coordination, cancellations, or reassignments**, which aligns with the high cancellation statistics observed.

Most importantly, **repeated customers remain very low at just 1,206**, which is minimal relative to total bookings. This suggests that Uber's 2024 performance is driven more by **one-time or occasional users** than by a loyal customer base. High cancellation rates—especially driver-initiated and pickup-related issues—likely contribute to this retention gap. While operational performance and revenue are strong, improving **ride reliability, pickup accuracy, and cancellation reduction**, along with targeted loyalty and incentive programs, represents the biggest opportunity to increase repeat usage and long-term customer value.
